

Software Engineering Seminar

Semantics based Automated Program Repair

Description

Automated program repair is a relatively new research field that is currently explored by many research groups using different strategies. One very interesting and promising method uses semantic information to repair a fault, i.e. it analyzes the behavior of the given program. The methodology behind this repair approach is that a repair candidate (a patch) is synthesized by using semantic information that is provided by, for example, symbolic execution and constraint solving. A state-of-the-art semantics based repair tool is ANGELIX [1] which is the successor of SEMFIX [2]. A main goal of ANGELIX is to scale to larger, real-world programs to be able to compete with other repair strategies like, for example, search-based automated repair.

The student is to examine and discuss the current state of semantics based automated program repair.
