- Example

## Networks

## How do we know? What does the network tell us?

## Approaches to Network Reconstruction

- By many, many small-scale experiments
- By mathematical modeling from high-throughput data sets
- By evolutionary inference from model organisms
- By curation from the literature (see first bullet)

## Reconstruction from Indirect High-Throughput Data

- Network reconstruction, re-engineering, inference, ...
- Idea: Derive network from indirect observations
- Network: Links and their effect (strength, activation, ...)
- We usually assume the players (genes, metabolites, ...) to be given
- Observation: High-throughput measurements
- Here: Transcriptome, microarrays, RNA-Seq
- Indirect: We try to infer mechanistic causality by correlation
- Dynamic networks
- Nodes get states (active / passive)
- Current states determine future states of nodes
- Leads to dynamic behavior
- Warning: All current methods are highly reductionist

## Boolean Network Models

- Definition

A Boolean Network is a digraph $G=(V, E)$ where

- Every node has an associated Boolean state (on/off)
- Every node is labeled with a Boolean function over the states of all incoming nodes
- Usage
- Vertices = genes
- Edge ( $v, w$ ) models an effect of $v$ on $w$
- The state of a node $v$ is determined by its Boolean function over all "incoming" states

$f_{A}(B)=B$
$f_{B}(A, C)=A$ and $C$
$f_{C}(A)=\operatorname{not} A$
Boolean Network
- Simplistic: No cofactors, no cellular context, no binding affinity, no time, no kinetics, ...

## Network Dynamics

- Definition

A Dynamic Boolean Network (DBN) is a Boolean network where every node $v$ is assigned a sequence of states $v_{0}, v_{1}, v_{2}, \ldots$ such that the state of $v_{t}$ is defined over the Boolean function of $v$ applied to the states $w_{t-1}$ of all incoming nodes w

- Remarks
- Models the state of every gene (on / off) over time
- States at time point t (only) depend on states at time point t-1
- No buffering, synchronized time, ...
- Deterministic: Given all states at any time point $t$ and the Boolean functions, any state at any later time point can be uniquely determined

## Example

Boolean Network Wiring Diagram

| State | INPUT |  |  | OUTPUT |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | A | B | C | $A^{\prime}$ | $B^{\prime}$ | $C^{\prime}$ |
| 1 | 0 | 0 | 0 | 0 | 0 | 1 |
| 2 | 0 | 0 | 1 | 0 | 0 | 1 |
| 3 | 0 | 1 | 0 | 1 | 0 | 1 |
| 4 | 0 | 1 | 1 | 1 | 0 | 1 |
| 5 | 1 | 0 | 0 | 0 | 0 | 0 |
| 6 | 1 | 0 | 1 | 0 | 1 | 0 |
| 7 | 1 | 1 | 0 | 1 | 0 | 0 |
| 8 | 1 | 1 | 1 | 1 | 1 | 0 |

Transition table

## Example

Boolean Network

| genes <br> time | $\mathbf{A}$ | $\mathbf{B}$ | $\mathbf{C}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{0}$ | 1 | 1 | 0 |
| $\mathbf{1}$ | 1 | 0 | 0 |
| $\mathbf{2}$ | 0 | 0 | 0 |
| $\mathbf{3}$ | 0 | 0 | 1 |
| $\mathbf{4}$ | 0 | 0 | 1 |
| $\mathbf{5}$ | $\ldots$ | $\ldots$ | $\ldots$ |

## Network Analysis

- Many things can be analyzed using DBN
- For instance, an attractor is a (set of) states towards which the network state converges
- Point attractor: State which cannot be left any more
- Cyclic attractor: A series of states which will repeat forever
- Probability of attractors depend largely on size of network and complexity of Boolean functions
- Skipped - we want to reconstruct networks

## Network Reconstruction

- Assume we know all genes, but not their relationships
- Assume we observe the states of n genes over $m$ time points (a matrix S ; the observations)
- Can we re-engineer the Boolean function of every gene given a sequence of states?

| genes <br> time | $\mathbf{A}$ | $\mathbf{B}$ | $\mathbf{C}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{0}$ | 1 | 1 | 0 |
| $\mathbf{1}$ | 0 | 0 | 1 |
| $\mathbf{2}$ | 1 | 0 | 0 |
| $\mathbf{3}$ | 1 | 1 | 0 |
| $\mathbf{4}$ | 0 | 0 | 1 |
| $\mathbf{5}$ | $\ldots$ | $\ldots$ | $\ldots$ |

## Network Reconstruction

- Assume we know all genes, but not their relationships
- Assume we observe the states of $n$ genes over $m$ time points (a matrix S ; the observations)
- Can we re-engineer the Boolean function of every gene given a sequence of states?

$f(A)=$ not $B$
$f(B)=A$ and not $B$
$f(C)=B$

| genes <br> time | $\mathbf{A}$ | $\mathbf{B}$ | $\mathbf{C}$ |
| :---: | :---: | :---: | :---: |
| $\mathbf{0}$ | 1 | 1 | 0 |
| $\mathbf{1}$ | 0 | 0 | 1 |
| $\mathbf{2}$ | 1 | 0 | 0 |
| $\mathbf{3}$ | 1 | 1 | 0 |
| $\mathbf{4}$ | 0 | 0 | 1 |
| $\mathbf{5}$ | $\ldots$ | $\ldots$ | $\ldots$ |

## Formal Problem

- Definition

Let $S_{t} 0 \leq t \leq m$, be the vector of all observed states of all genes $V$ at time point $t$. A $D B N G=(V, E)$ with functions $f_{1}, \ldots f_{r} n=/ V /$, is called

- consistent with $S_{t}$ iff $S_{t}=\left[f_{1}\left(S_{t-1}\right), f_{2}\left(S_{t-1}\right), \ldots f_{n}\left(S_{t-1}\right)\right]$
- consistent with $S$ iff it is consistent for all $S_{t} 1 \leq t \leq m$
- The Boolean network reconstruction problem Given an observation S over a set V, find a DBN G=(V,E) that is consistent with $S$.
- Remark
- Reconstruction means finding the functions $f_{1}, \ldots f_{n}$
- This also determines network topology (nodes appearing in a $f_{i}$ )

## Solutions

- Clearly, there are many observations S for which no consistent G exists
- Recall that DBN are deterministic
- Imagine $\mathrm{S}_{\mathrm{t}}, \mathrm{S}_{\mathrm{t}+1}$ and $\mathrm{S}_{\mathrm{u}}, \mathrm{S}_{\mathrm{u}+1}$ with $\mathrm{S}_{\mathrm{t}}=\mathrm{S}_{\mathrm{u}}$ but $\mathrm{S}_{\mathrm{t}+1} \neq \mathrm{S}_{\mathrm{u}+1}$
- Also, there are many observation S for which more than one consistent G exists
- Every time point narrows the options for G - the longer S, the less (or no) consistent G's exist

## Optimal Networks

- Definition
- For a DBN G, let size(G) be the total number of variables (edges) appearing in the Boolean functions of $G$
- A DBN $G$ is minimal for observation $S$, if $G$ is consistent with $S$ and there is no $G^{\prime}$ which is also consistent with $S$ and size $\left(G^{\prime}\right)<\operatorname{size}(G)$
- Remark
- Parsimony assumption: Small models are better
- Thus, the smallest network is the best - functions are as simple as possible, nothing is inferred that is not enforced by the data
- Not necessarily unique

## Naïve Algorithm

```
N = V;
for k=1..n # length of functions
    for every n in N # all unexplained nodes
        test all functions f of size k for n on S;
        if f is consistent for n on S
            N := N \ n; # n is explained
            Add f to network;
        end if;
    end for;
end for;
```

- Exhaustive algorithm for finding minimal networks
- Very complex (AND, OR, NOT, no paranthesis)
- $k=1$ : $2 n$ functions
- $k=2: 2 * 2 n * 2 n=O\left(n^{2}\right)$ functions
-"•
- General: $O\left(2^{2 k-1 *} n^{k}\right)$ functions

## Pros and Cons

- Application (transcriptome data)
- Perform time-series gene expression experiments
- Brutally discretize each measurement: Genes are on or off
- Reconstruct DBN
- Pros: Simple
- Cons
- Binary values are not capturing reality
- Synchronized, clocked time is nonsense
- No quantification (It needs 2*A and one B to regulate C)
- Only small networks are computable
- ...

## Content

- Network reconstruction
- Boolean models
- Correlation-Based Approaches: REVEAL / ARACNE
- Example

## Towards Reality

- There are less complex \& more robust algorithms
- REVEAL replaces Boolean functions by mutual information; correlations rather than deterministic switching
- Liang, S., S. Fuhrman and R. Somogyi (1998). Reveal, a general reverse engineering algorithm for inference of genetic network architectures. Pacific Symposium on Biocomputing., Hawaii, US.
- ARACNE is even simpler: Only removal of some (presumably indirect) correlations
- Margolin, A. A., I. Nemenman, K. Basso, C. Wiggins, G. Stolovitzky, R. D. Favera and A. Califano (2006). "ARACNE: an algorithm for the reconstruction of gene regulatory networks in a mammalian cellular context." BMC Bioinformatics 7((Suppl 1), S7).

## Foundations

- Definition

Let $X, Y$ be two discrete random variables. The mutual information $M I(X, Y)$ is defined as

$$
M I(X, Y)=\sum_{x \in X} \sum_{y \in Y} p(x, y) * \log \left(\frac{p(x, y)}{p(x) * p(y)}\right)
$$

- Remark
- Measure the variable's mutual dependency
- Dependency: Deviation of $p(X, Y)$ from $p(X) * p(Y)$
- How much does the state of $X$ determines the state of $Y$ ?
- Many similar measures (information gain, conditional entropy, cross entropy, ...)

## Example

$$
M I(X, Y)=\sum_{x \in X} \sum_{y \in Y} p(x, y) * \log \left(\frac{p(x, y)}{p(x) * p(y)}\right)
$$

| $\mathbf{p}(\mathbf{x}, \mathbf{y})$ | $\mathbf{y}=\mathbf{0}$ <br> $\mathbf{p}(\mathbf{y}=\mathbf{0})=\mathbf{0} .6$ | $\mathbf{y}=\mathbf{1}$ <br> $\mathbf{p}(\mathbf{y}=\mathbf{1})=\mathbf{0 . 4}$ |
| :---: | :---: | :---: |
| $\mathbf{x}=\mathbf{0} ; \mathbf{p}(\mathbf{x}=\mathbf{0})=\mathbf{0 . 2}$ | 0,12 | 0,08 |
| $\mathbf{x}=\mathbf{1} ; \mathbf{p}(\mathbf{x}=\mathbf{1})=\mathbf{0 . 8}$ | 0,48 | 0,32 |

$\mathrm{Ml}(\mathrm{X}, \mathrm{Y})=0$

| $\mathbf{p}(x, y)$ | $\mathbf{y}=\mathbf{0}$ <br> $\mathbf{p}(\mathbf{y}=\mathbf{0})=\mathbf{0 . 6}$ | $\mathbf{y}=\mathbf{1}$ <br> $\mathbf{p}(\mathbf{y}=\mathbf{1})=\mathbf{0 . 4}$ |
| :---: | :---: | :---: |
| $\mathbf{x}=\mathbf{0} ; \mathbf{p}(\mathbf{x}=\mathbf{0})=\mathbf{0 . 2}$ | 0,18 | 0,03 |
| $\mathbf{x}=\mathbf{1} ; \mathbf{p}(\mathbf{x}=\mathbf{1})=\mathbf{0 . 8}$ | 0,05 | 0,74 |

$\mathrm{Ml}(X, Y)=0,53$

## Two more Facts

- With a little math, we find

$$
M I(X, Y)=H(X)-H(X \mid Y)=H(Y)-H(Y \mid X)
$$

- $H(X)$ : Entropy of $X$
- $\mathrm{H}(\mathrm{X} \mid \mathrm{Y})$ : Conditional entropy of X given Y
- It follows that the maximal value of $\mathrm{MI}(\mathrm{X}, \mathrm{Y})=\mathrm{H}(\mathrm{X})(\mathrm{H}(\mathrm{Y}))$
- $H(X \mid Y)=0$, which means that $X(Y)$ completely determines $Y(X)$
- MI can be extended to sets of three, four, ... variables
- Like Boolean functions over three, four, ... variables
- Multivariate mutual information

## REVEAL

```
N = V;
for k=1...n # number of nodes/variables
    for every X in N # all unexplained nodes
        find subset T=(Y , ...Y ( ) with MI(X, Y , ...Y ( ) = H(X);
        if T exists
        N := N \ X; # n is explained
    end for;
end for;
```

- Again, we have observations of n genes at m time points
- Or m different conditions, treatments, ...
- Again, we discretize expression values to 0 or 1
- More bins are possible
- MI $(X, Y)$ means looking at pairs $\left(x_{1}, y_{0}\right),\left(x_{2}, y_{1}\right), \ldots$

## REVEAL in Practice

- In the formulation given, REVEAL would be as strict as Boolean functions
- Dependencies must be perfect
- In the presence of noise, one must be satisfied with almost maximal MI
- l.e., $|\mathrm{MI}(\mathrm{X}, \mathrm{Y})-\mathrm{H}(\mathrm{X})|<\varepsilon$
- Can be extended to more than two possible states
- Less strict discretization, more realistic model
- Most other restrictions of DBN remain

## ARACNE

- Fast variation of REVEAL which (a) considers each pair in isolation and (b) gives up model minimality
- Idea
- Compute mutual information between all pairs of genes
- This gives a complete network
- Remove edges where $|\mathrm{Ml}(\mathrm{X}, \mathrm{Y})-\mathrm{H}(\mathrm{X})|>\varepsilon$
- $\varepsilon$ can be estimated from the distribution of Ml - created at random?
- Remove certain indirect effects ("data processing inequalities")
- Under certain assumptions, ARACNE provably converges to the true network
- Given unlimited input, no loops
- "True": Under all networks obeying our simplifying assumptions

## Data Processing Inequalities

- Assumption: If $\operatorname{MI}(X, Z) \leq \min (M I(X, Y), M I(Y, Z))$, then the correlation between $X-Z$ is an indirect effect and removed
- Procedural: In every triangle, remove the smallest edge
- But in which order should triangles be visited?

| 5 | Hagenexch | 15.645 | 12.708 | 12.708 | 15.648 | 0.208 | 0.094 |

- Filtering of ARACNE reduces recall a lot, while precision increases only marginally
- Data set size outweighs specificity - reconstruction about as good using many untargeted arrays or using fewer targeted arrays
